

Package ‘PathQuant’

January 8, 2023

Type Package

Title Annotation of gene-metabolite pairs using topology of KEGG metabolic pathway maps

Version 0.1.0

Date 2023-01-01

Author Cantin Baron <cantin.baron@umontreal.ca>
Sandra Therrien-Laperriere <sandra.therrien.laperriere@gmail.com>
Sarah Cherkaoui <cherkaos@gmail.com>

Maintainer Cantin Baron <cantin.baron@umontreal.ca>

Description Modeling of KEGG metabolism pathway maps into compound graph format to compute shortest reactional distance (SRD) for gene-metabolite pairs to assess their biological relevance and output results in data.frame and graphical outputs.

srd.distribution	7

Index**8**

`annotateAssociationData`*Gene annotation classification of associations*

Description

Gene annotation involve EC number, kegg brite annotation High level classification made by involved brite trnasporter, enzyme or protein

Usage

```
annotateAssociationData(associations)
```

Arguments

<code>association</code>	Dataframe with 2 columns, where each line represents an association. First column are the genes and the second column are the metabolites. Only use KEGG IDs.
--------------------------	---

Examples

```
annotateAssociationData(associations)
```

`exportDFtoTxt`*Export results data of a data frame into a text files, for which each lines separates the data from every data frame column by tabulation. This text file can be easily opened with excel.*

Description

Export results data of a data frame into a text files, for which each lines separates the data from every data frame column by tabulation. This text file can be easily opened with excel.

Usage

```
exportDFtoTxt(export_data, exportNameFile)
```

Arguments

<code>a</code>	dataframe.
----------------	------------

Examples

```
exportDFtoTxt(dataFrame, exportFileName)
```

gene.distribution	<i>Distance distribution plots for single gene</i>
-------------------	--

Description

Function plotting the distribution of distances between a gene and all measured metabolite, highlighting the distance of its associated metabolites.

Usage

```
gene.distribution(pathway, gene, pairs, metabolites)
```

Arguments

pathway	Selected pathway. Only use KEGG Ids.
gene	Gene selected. Only use KEGG Ids.
pairs	Dataframe with 2 columns, where each line represents an association. First column are the genes and the second column are the metabolites. Only use KEGG Ids.
metabolites	Dataframe of 1 column containing a list of selected metabolites. Default = "All". All metabolite of the selected pathway map. Only use KEGG Ids.

Details

The plot is depicted as frequency bars, which represent the number of metabolites at a given distance for the selected gene. Frequency bars are shown in grey for metabolites that are not associated with the selected gene and in red if there is at least one metabolite associated with this gene.

If a gene or a metabolite is present on multiple edges or nodes, then the shortest distance is selected.

Examples

```
gene.distribution(hsa01100, "hsa:1373" , pairs.df, metabolite.df)
```

get.srd	<i>isGeneInMap, metaboliteCommonName, metaboliteKEGGId, isMetaboliteInMap, distance</i>
---------	---

Description

isGeneInMap, metaboliteCommonName, metaboliteKEGGId, isMetaboliteInMap, distance

Usage

```
get.srd(pairs, organism_code, pathway = "All", ordered = FALSE,
        commonNames = FALSE, path = FALSE,
        computer_path_to_map_folder = "")
```

Arguments

pairs	dataframe with 2 columns, where each line represents a pair. The first column is genes and the second column is metabolites. Only use KEGG Ids.
pathway	list of selected metabolic pathway in KEGG. Default = "All". Only use KEGG Ids.
ordered	[option] ascendent ordering of distance
commonNames	[option] get KEGG's Common Names of the KEGG Id in the results.
path	[option] get reactional path used for srd computation.

Examples

```
get.srd(pairs.df, "All")
```

heatmap	<i>Function that output a heatmap to visualize distance computed between every gene-metabolite associations in input using the overview map only</i>
---------	--

Description

Function computing shortest distance between every genes and metabolites in a gene-metabolite pairs of your association dataset on a graph model of KEGG map selected, where nodes are metabolites and reactions/genes are edges.

Usage

```
heatmap(association, pathway, computer_path_to_map_folder,
        commonNames = TRUE)
```

Arguments

association	dataframe with 2 columns, where each line represents a unique association. First column are genes and second column are metabolites. Only use KEGG Ids.
pathway	KEGG Id.
display	common names of KEGG ids input (TRUE) or display KEGG Ids for axis description.

Details

If a gene or a metabolite is present on multiple edges or nodes, then the shortest distance is selected within the group

Output: Heatmap of distances calculated between associated genes-metabolites. Columns represent genes and rows represent metabolites. The calculated distance is shown in each cell with the corresponding color code (from red - closest; to yellow - farthest).

Examples

```
heatmap(shinAndA1DF, TRUE)
```

importTXTtoDF	<i>Importing data from an txt file (with table separators), in the context of this package, one of the data to import is the association file.</i>
---------------	--

Description

Importing data from an txt file (with table separators), in the context of this package, one of the data to import is the association file.

Usage

```
importTXTtoDF(file)
```

Arguments

path to txt file.

Examples

```
inputXLSXtoDF("file_path/fileName.xlsx")
```

importXLSXtoDF	<i>Importing data from an XSLX file, in the context of this package, one of the data to import is the association file.</i>
----------------	---

Description

Importing data from an XSLX file, in the context of this package, one of the data to import is the association file.

Usage

```
importXLSXtoDF(file, sheet.num = 1)
```

Arguments

path to XSLX file.

Examples

```
inputXLSXtoDF("file_path/fileName.xlsx")
```

permutationTest	<i>Statistical permutation test to asses the relevance of associated gene-metabolite pairs vs. randomly selected pairs</i>
-----------------	--

Description

Permutation test to evaluate if gene-metabolite associations are significantly closer than randomly selected gene-metabolite pairs.

Usage

```
permutationTest(pathwayId, association, gene, metabolite, permutation,
  output = c("medians", "pvalue", "histogram"))
```

Arguments

pathwayId	KEGG Id of selected pathway.
association	Dataframe with 2 columns, where each line represents an association. First column are genes and the second column are metabolites. Only use KEGG Ids.
gene	Dataframe of 1 column, representing all genes reported. Only use KEGG Ids.
metabolite	Dataframe of 1 column, representing all the measured metabolites. Only use KEGG Ids.
permutation	Number desired permutations
output	'medians' of all permutations, 'pvalue' of the permutation test, 'histogram' representing the distribution of all permutations' median

Details

If a gene or a metabolite is present on multiple edges or nodes, then the shortest distance is selected.

Examples

```
permutationFunction("hsa01100", shinAndAIDF,
  completeGeneDF, completeMetaboDF, 1000, "histogram")
```

srd.distribution	<i>srd.distribution</i>
------------------	-------------------------

Description

Function plotting the distribution of srds computed by get.srd function.

Usage

```
srd.distribution(distance)
```

Arguments

distance	list of computed srd values of the data.frame obtained by get.srd function
----------	--

Details

The plot is depicted as frequency bars, which represent the number of pairs at a given srd value. Frequency bars are shown in heatmap colors to depict the small from larger srd values.

Examples

```
srd.distribution(res[,7])
```
